Model Objectives

- French guidelines recommend the use of atypical antipsychotics as a first line treatment for new onset schizophrenia*.
- Typical antipsychotics cost less (generic forms available) but have more side effects (extrapyramidal symptoms).
- What is the economical burden of antipsychotic prescription for schizophrenia and how is it supposed to evolve?

METHODS
Data Sources: “EpiSurvey”

- Cross-sectional epidemiological survey;
- Representative sample of ambulatory schizophrenic patients;
- 177 psychiatrists surveyed:
  - 116 in private practice;
  - 61 in hospital consultations (out-patients).

- Two-level survey:
  - Patient registry: 2732 patients ➔ Treatment patterns
  - Detailed survey: 1855 patients ➔ Treatment switches
General Markov Model

• 6 classes of antipsychotics can be prescribed as the principal treatment;
• Patients can switch between these six treatments (or remain under their treatment);
• $6 \times 6 = 36$ transition probabilities;
• 3 one-year cycles simulated.

4 Markov Models

- Patients stratified according to age in 2003 and prescription settings (hospital/private practice).
- Differing transition probabilities.
- Every year, patients:
  - Enter the “Age < 42” models;
  - Leave the “Age ≥ 42” models;
  - Total entry proportion = total exit proportion (stable prevalence in France).

Cost of principal antipsychotic taken (cost of co-prescriptions not included).

- **Budget increase from 2003 to 2006:** +12.3%
- **Estimated confidence interval:** [8.3% - 18.6%]
CONCLUSION

Schizophrenia treatment patterns are not stationary;
Simple Markov-based models can help understand the evolution of prescriptions;
Average daily treatment cost is expected to increase in the next years.
